

## Chapter 42 Serial Peripheral Interface (SPI)

### 42.1 Overview

The serial peripheral interface is an APB slave device. A four wire full duplex serial protocol from Motorola. There are four possible combinations for the serial clock phase and polarity. The clock phase (SCPH) determines whether the serial transfer begins with the falling edge of slave select signals or the first edge of the serial clock. The slave select line is held high when the SPI is idle or disabled. This SPI controller can work as either master or slave mode.

SPI Controller supports the following features:

- Support Motorola SPI, TI Synchronous Serial Protocol and National Semiconductor Microwire interface
- Support 32-bit APB bus
- Support two internal 16-bit wide and 32-location deep FIFOs, one for transmitting and the other for receiving serial data
- Support two chip select signals in master mode
- Support 4, 8, 16 bit serial data transfer
- Support configurable interrupt polarity
- Support asynchronous APB bus and SPI clock
- Support master and slave mode
- Support DMA handshake interface and configurable DMA water level
- Support transmit FIFO empty, underflow, receive FIFO full, overflow, interrupt and all interrupts can be masked
- Support configurable water level of transmit FIFO empty and receive FIFO full interrupt
- Support combine interrupt output
- Support up to half of SPI clock frequency transfer in master mode and one sixth of SPI clock frequency transfer in slave mode
- Support full and half duplex mode transfer
- Stop transmitting SCLK if transmit FIFO is empty or receive FIFO is full in master mode
- Support configurable delay from chip select active to SCLK active in master mode
- Support configurable period of chip select inactive between two parallel data in master mode
- Support big and little endian, MSB and LSB first transfer
- Support two 8-bit audio data store together in one 16-bit wide location
- Support sample RXD 0~3 SPI clock cycles later
- Support configurable SCLK polarity and phase
- Support fix and incremental address access to transmit and receive FIFO

### 42.2 Block Diagram

The SPI Controller comprises with:

- AMBA APB interface and DMA Controller Interface
- Transmit and receive FIFO controllers and an FSM controller
- Register block
- Shift control and interrupt

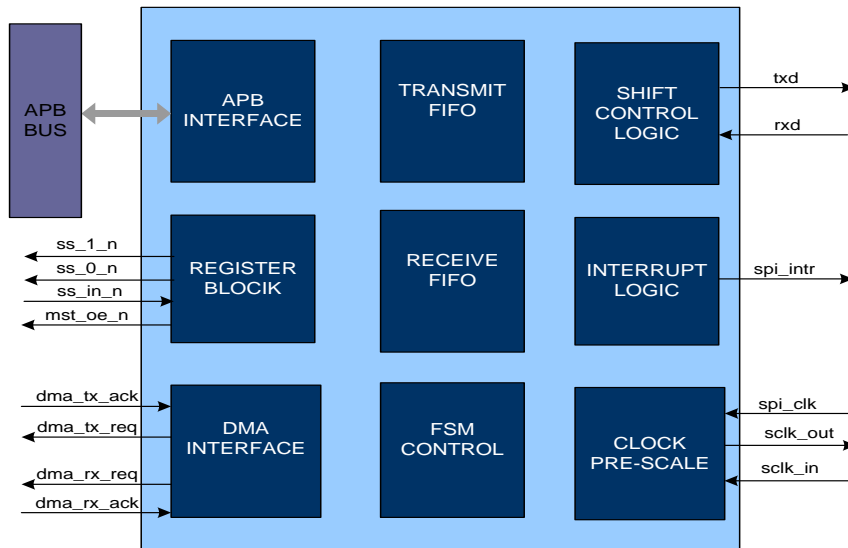

Fig. 42-1 SPI Controller Block diagram

**APB INTERFACE**

The host processor accesses data, control, and status information on the SPI through the APB interface. The SPI supports APB data bus widths of 8, 16, and 32 bits.

**DMA INTERFACE**

This block has a handshaking interface to a DMA Controller to request and control transfers. The APB bus is used to perform the data transfer to or from the DMA Controller.

**FIFO LOGIC**

For transmit and receive transfers, data transmitted from the SPI to the external serial device is written into the transmit FIFO. Data received from the external serialdevice into the SPI is pushed into the receive FIFO. Both fifos are 32x16bits.

**FSM CONTROL**

Control the state’s transformation of the design.

**REGISTER BLOCK**

All registers in the SPI are addressed at 32-bit boundaries to remain consistent with the AHB bus. Where the physical size of any register is less than 32-bits wide, the upper unused bits of the 32-bit boundary are reserved. Writing to these bits has no effect; reading from these bits returns 0.

**SHIFT CONTROL**

Shift control logic shift the data from the transmit fifo or to the receive fifo. This logic automatically right-justifies receive data in the receive FIFO buffer.

**INTERRUPT CONTROL**

The SPI supports combined and individual interrupt requests, each of which can be masked. The combined interrupt request is the ORed result of all other SPI interrupts after masking.

## 42.3 Function description

Fig. 42-2 SPI Master and Slave Interconnection

The SPI controller support dynamic switching between master and slave in a system. The diagram show how the SPI controller connects with other SPI devices.

### Operation Modes

The SPI can be configured in the following two fundamental modes of operation: Master Mode when SPI\_CTRLR0 [20] is 1'b0, Slave Mode when SPI\_CTRLR0 [20] is 1'b1.

### Transfer Modes

The SPI operates in the following three modes when transferring data on the serial bus.

#### 1. Transmit and Receive

When SPI\_CTRLR0 [19:18] == 2'b00, both transmit and receive logic are valid.

#### 2. Transmit Only

When SPI\_CTRLR0 [19:18] == 2'b01, the receive data are invalid and should not be stored in the receive FIFO.

#### 3. Receive Only

When SPI\_CTRLR0 [19:18] == 2'b10, the transmit data are invalid.

### Clock Ratios

A summary of the frequency ratio restrictions between the bit-rate clock (sclk\_out / sclk\_in) and the SPI peripheral clock (spi\_clk) are described as,

When SPI Controller works as master, the  $F_{spi\_clk} \geq 2 \times (\text{maximum } F_{sclk\_out})$

When SPI Controller works as slave, the  $F_{spi\_clk} \geq 6 \times (\text{maximum } F_{sclk\_in})$

With the SPI, the clock polarity (SCPOL) configuration parameter determines whether the inactive state of the serial clock is high or low. To transmit data, both SPI peripherals must have identical serial clock phase (SCPH) and clock polarity (SCPOL) values. The data frame can be 4/8/16 bits in length.

When the configuration parameter SCPH = 0, data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the txd and rxd lines prior to the first serial clock edge. The following two figures show a timing diagram for a single SPI data transfer with SCPH = 0. The serial clock is shown for configuration parameters SCPOL = 0 and SCPOL = 1.

Fig. 42-3 SPI Format (SCPH=0 SCPOL=0)

Fig. 42-4 SPI Format (SCPH=0 SCPOL=1)

When the configuration parameter  $SCPH = 1$ , both master and slave peripherals begin transmitting data on the first serial clock edge after the slave select line is activated. The first data bit is captured on the second (trailing) serial clock edge. Data are propagated by the master and slave peripherals on the leading edge of the serial clock. During continuous data frame transfers, the slave select line may be held active-low until the last bit of the last frame has been captured. The following two figures show the timing diagram for the SPI format when the configuration parameter  $SCPH = 1$ .

**SPI\_CTRLR1**

Address: Operational Base + offset (0x0004)

Control Register 1

Bit	Attr	Reset Value	Description
31:16	RO	0x0	reserved
15:0	RW	0x0000	<p>NDM Number of Data Frames When Transfer Mode is receive only, this register field sets the number of data frames to be continuously received by the SPI. The SPI continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 64 KB of data in a continuous transfer.</p>

**SPI\_ENR**

Address: Operational Base + offset (0x0008)

SPI Enable

Bit	Attr	Reset Value	Description
31:1	RO	0x0	reserved
0	RW	0x0	ENR SPI Enable Enables and disables all SPI operations. Transmit and receive FIFO buffers are cleared when the device is disabled.

**SPI\_SER**

Address: Operational Base + offset (0x000c)

Slave Enable Register

Bit	Attr	Reset Value	Description
31:2	RO	0x0	reserved
1:0	RW	0x0	SER Slave Select Enable This register is valid only when SPI is configured as a master device.

**SPI\_BAUDR**

Address: Operational Base + offset (0x0010)

Baud Rate Select

Bit	Attr	Reset Value	Description
31:16	RO	0x0	reserved
15:0	RW	0x0000	BAUDR Baud Rate Select SPI Clock Divider. This register is valid only when the SPI is configured as a master device. The LSB for this field is always set to 0 and is unaffected by a write operation, which ensures an even value is held in this register. If the value is 0, the serial output clock (sclk_out) is disabled. The frequency of the sclk_out is derived from the following equation: $F_{sclk\_out} = F_{spi\_clk} / SCKDV$ Where SCKDV is any even value between 2 and 65534. For example: for $F_{spi\_clk} = 3.6864\text{MHz}$ and $SCKDV = 2$ $F_{sclk\_out} = 3.6864/2 = 1.8432\text{MHz}$

**SPI\_TXFTLR**

Address: Operational Base + offset (0x0014)

Transmit FIFO Threshold Level

Bit	Attr	Reset Value	Description
-----	------	-------------	-------------

Bit	Attr	Reset Value	Description
31:5	RO	0x0	reserved
4:0	RW	0x00	TXFTLR Transmit FIFO Threshold Level When the number of transmit FIFO entries is less than or equal to this value, the transmit FIFO empty interrupt is triggered.

**SPI\_RXFTLR**

Address: Operational Base + offset (0x0018)

Receive FIFO Threshold Level

Bit	Attr	Reset Value	Description
31:5	RO	0x0	reserved
4:0	RW	0x00	RXFTLR Receive FIFO Threshold Level When the number of receive FIFO entries is greater than or equal to this value + 1, the receive FIFO full interrupt is triggered.

**SPI\_TXFLR**

Address: Operational Base + offset (0x001c)

Transmit FIFO Level

Bit	Attr	Reset Value	Description
31:6	RO	0x0	reserved
5:0	RO	0x00	TXFLR Transmit FIFO Level Contains the number of valid data entries in the transmit FIFO.

**SPI\_RXFLR**

Address: Operational Base + offset (0x0020)

Receive FIFO Level

Bit	Attr	Reset Value	Description
31:6	RO	0x0	reserved
5:0	RO	0x00	RXFLR Receive FIFO Level Contains the number of valid data entries in the receive FIFO.

## 42.6 Application Notes

### Clock Ratios

A summary of the frequency ratio restrictions between the bit-rate clock (sclk\_out/sclk\_in) and the SPI peripheral clock (spi\_clk) are described as,

When SPI Controller works as master, the  $F_{spi\_clk} \geq 2 \times (\text{maximum } F_{sclk\_out})$

When SPI Controller works as slave, the  $F_{spi\_clk} \geq 6 \times (\text{maximum } F_{sclk\_in})$

### Master Transfer Flow

When configured as a serial-master device, the SPI initiates and controls all serial transfers. The serial bit-rate clock, generated and controlled by the SPI, is driven out on the sclk\_out line. When the SPI is disabled (SPI\_ENR = 0), no serial transfers can occur and sclk\_out is held in "inactive" state, as defined by the serial protocol under which it operates.

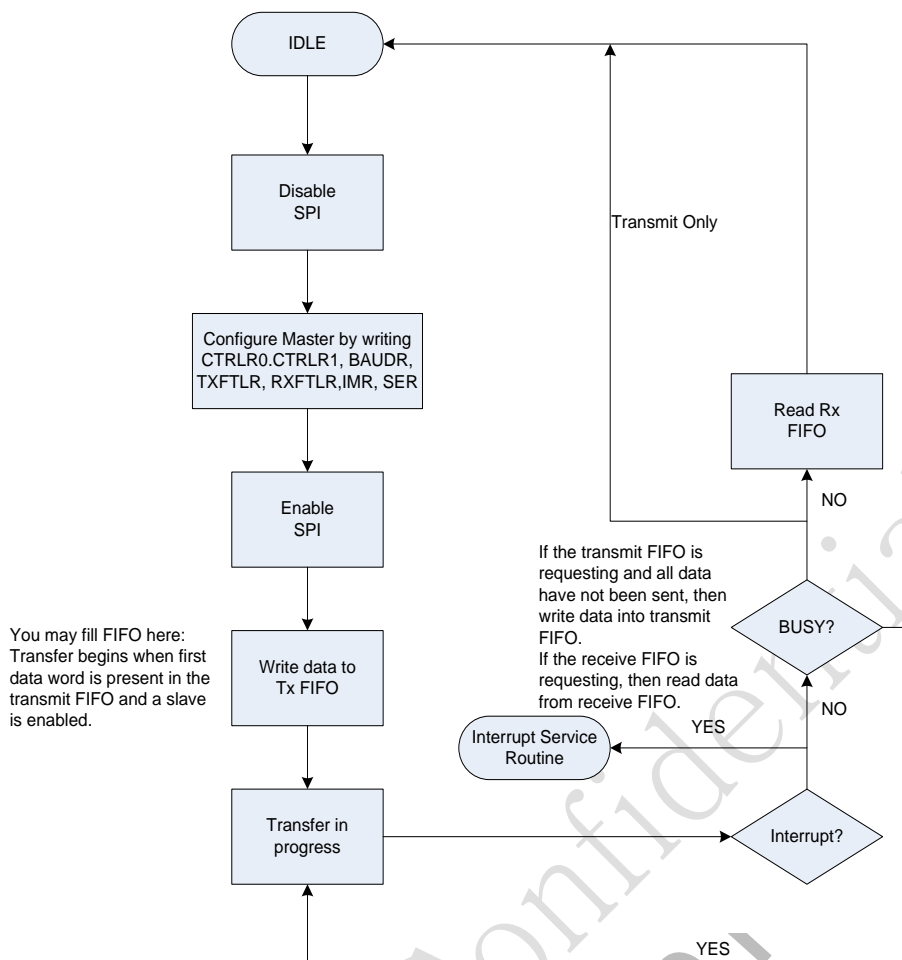

Fig. 42-7 SPI Master transfer flow diagram

**Slave Transfer Flow**

When the SPI is configured as a slave device, all serial transfers are initiated and controlled by the serial bus master.

When the SPI serial slave is selected during configuration, it enables its txd data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (sclk\_in), driven from the serial-master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge.

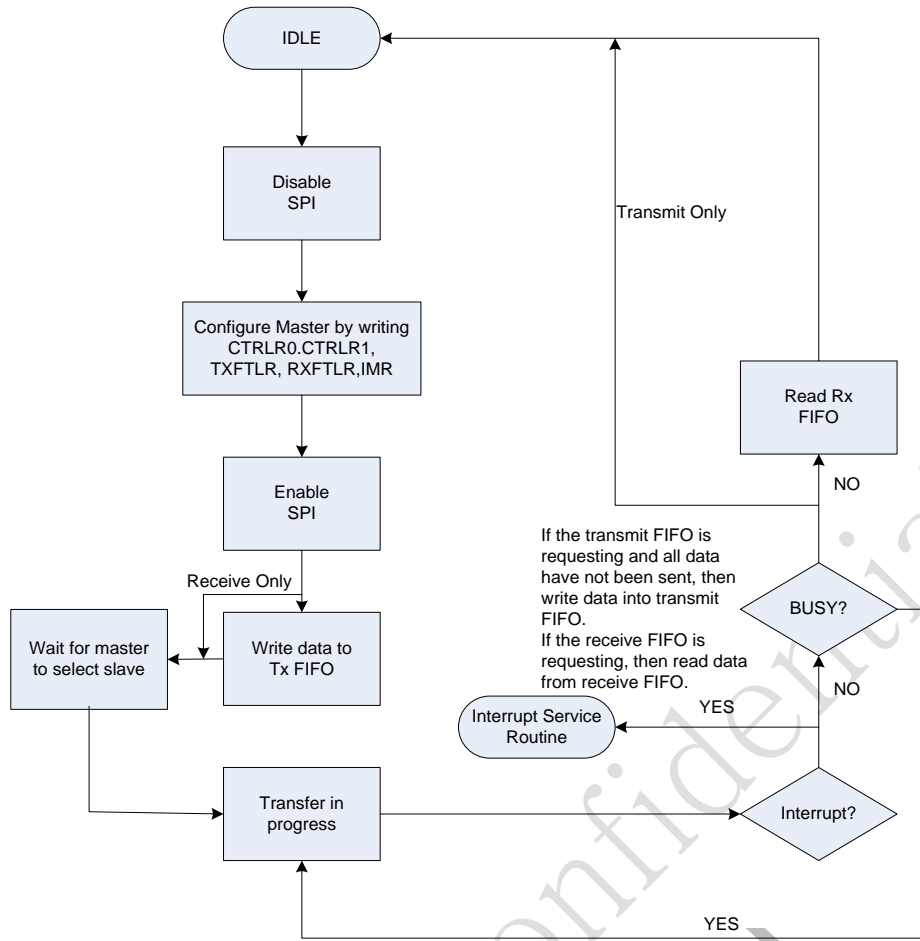

Fig. 42-8 SPI Slave transfer flow diagram
